# Gaussian Quadrature

### Arunima Sarkar

## 1 Singular integrals

The integral that have to be computed is:

$$J = \int_{1}^{3} \frac{e^{-x}}{J_{1}(\sqrt{-x^{2} + 4x - 3})} dx \tag{1}$$

### 1.1 Graphing the integrand in python

The corresponding code is:

```
import matplotlib.pyplot as plt
import plotly.graph_objects as go
import scipy.special as sp
import math as m
import numpy as np
import seaborn as sns
def integrand(x):
    return np.\exp(-x)/ \text{sp.jv}(1, \text{np.sqrt}(-x**2 + 4*x - 3))
initial=1e-7
x=np.linspace(1+initial,3-initial,1000)
y=integrand(x)
fig = go.Figure()
fig.add_trace(go.Scatter(
    x=x,
    y=y
))
fig.update_layout(title="F(x) vs x",
    xaxis_title="Values in x",
```

```
\label{eq:continuous_state} \begin{array}{c} yaxis\_title="f(x)", yaxis\_type="log",\\ & font=dict(\\ family="Courier New, monospace",\\ & size=18,\\ & color="RebeccaPurple"\\ ))\\ fig.show() \end{array}
```

## F(x) vs x

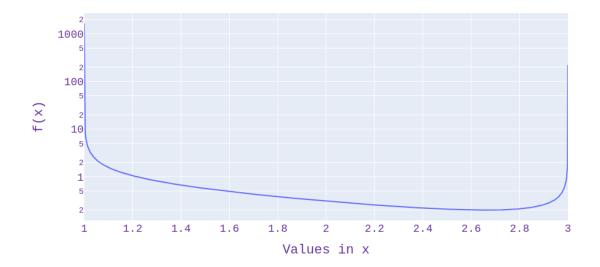

Figure 1

We can clearly see that there are two discontinuities at x = 1 and at x = 3.

### 1.2 Using quad

The code:

```
import scipy.integrate as si
ans=si.quad(integrand,1,3,full_output=0)
print(ans)
```

The value of the integral in eq(1) achieved is 1.140489938554265 and the error is  $5.333975483523545 \times 10^{-10}$ . If we make the 4th argument any non-zero value then number of evaluation of the function is shown which in this case is 567.

### 1.3 Using Open Romberg

```
import sing_intg as rom ans=rom.qromo(integrand ,1, ,3, ,1, e-4) print (ans) # Requires 81 function calls and error is of order 6 import sing_intg as rom ans=rom.qromo(integrand ,1, ,3, ,1, e-5) print (ans) #Requires 81 function calls and error is of order 6 import sing_intg as rom ans=rom.qromo(integrand ,1, ,3, ,1, e-6) print (ans) #Requires 2187 function calls and error is of order 6 import sing_intg as rom ans=rom.qromo(integrand ,1, ,3, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1, ,1,
```

The number of function calls drastically increases with decreasing epsilon values in gromb.

### 1.4 Transforming the integrand

Here we are applying a transformation where x=t+2 on eq(1). The equation is:

$$J = \int_{-1}^{1} \frac{e^{-t-2}}{J_1(\sqrt{1-t^2})} dt = \int_{-1}^{0} \frac{e^{-t-2}}{J_1(\sqrt{1-t^2})} dt + \int_{0}^{1} \frac{e^{-t-2}}{J_1(\sqrt{1-t^2})} dt$$
 (2)

According to Numerical recipes in C, the mentioned transformations on improper integrals are done, I also broke the integral from -1 to 0 and 0 to 1 and carried out the following transformation,

when singularity is in a,

$$\int_{a}^{b} f(x) = \frac{1}{1 - \gamma} \int_{0}^{(b-a)^{(1-\gamma)}} t^{\frac{\gamma}{1-\gamma}} f(t^{\frac{1}{1-\gamma}} + a) dt, \quad b > a$$
 (3)

So our equation (2),

$$J = \int_{-1}^{0} \frac{e^{-t-2}}{J_1(\sqrt{1-t^2})} dt \tag{4}$$

upon transformation looks like,

$$\int_{0}^{1} 2mf(m^{2} - 1)dm \tag{5}$$

when singularity is in b, the transformation is,

$$\int_{a}^{b} f(x) = \frac{1}{1 - \gamma} \int_{0}^{(b-a)^{(1-\gamma)}} t^{\frac{\gamma}{1-\gamma}} f(b - t^{\frac{1}{1-\gamma}}) dt, \quad b > a$$
 (6)

So our equation (2),

$$J = \int_0^1 \frac{e^{-t-2}}{J_1(\sqrt{1-t^2})} dt \tag{7}$$

upon transformation looks like,

$$\int_{0}^{1} 2mf(1-m^{2})dm \tag{8}$$

### Code

```
ans11=rom.qromo(ne_integrand_1,0,1,1e-5)
ans22=rom.qromo(ne_integrand_2,0,1,1e-5)
Integral=ans11[0]+ans22[0]
error=ans11[1]+ans22[1]
print(Integral)
print("Error is",error)
```

And upon applying romberg upon this we get a lower order error,  $1.688269168388129e \times 10^{-11}$  and even the number of function calls are also less, which is 81.

# 2 Gaussian Quadratures

We have to just compute  $x_j$  and  $w_j$ , which are given by below formulas,

$$x_j = \cos\frac{\pi(j - \frac{1}{2})}{N} \tag{9}$$

$$w_j = \frac{\pi}{N} \tag{10}$$

Here N=20 is considered as exact value and the code has looped over till it reaches 20 and error is found by checking their values.

### Code:

```
 \begin{array}{l} \text{def } gq(x,w)\colon \\ s=0 \\ \text{for } i \text{ in } range(len(x))\colon \\ s+=new\_integrand(x[i])*w[i] \\ \text{return } s \\ \\ \text{def } exact()\colon \\ x=[] \\ w=[1]*20 \\ val=0 \\ \text{for } i \text{ in } range(1,21)\colon \\ x.\,append(np.\cos(np.pi*(i-0.5)/20)) \\ w[i-1]=w[i-1]*m.pi/20 \\ \text{return } gq(x,w) \\ \\ \text{errors}=[] \\ \text{for } i \text{ in } range(1,21)\colon \\ \end{array}
```

```
 \begin{array}{l} {\rm xi} \!\!=\! \!\! {\rm np.\,array} \, (\, {\rm range} \, (\, 1\, ,\, i\, \! +\! 1)) \\ {\rm xi} \!\!=\! \!\! {\rm np.\,cos} \, (\, {\rm np.\,pi} \, * (\, {\rm xi} \, -\! 0.5) / \, i\, ) \\ {\rm wi} \!\!=\! \!\! {\rm np.\,full} \, (\, i\, \, ,\! {\rm np.\,pi} / \, i\, ) \\ {\rm errors.\,append} \, (\, {\rm np.\,abs} \, (\, {\rm gq} \, (\, {\rm xi} \, \, ,\! {\rm wi}) \! -\! {\rm exact} \, (\, )\, )\, ) \end{array}
```

The graph for Number of points(N) Vs Order of error.

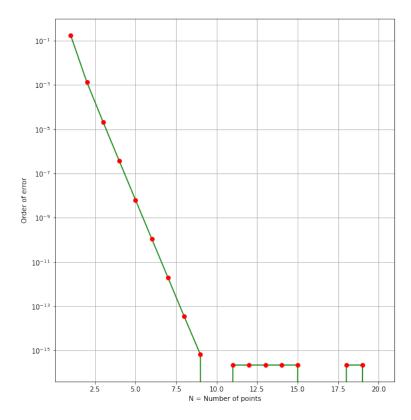

Figure 2

# 3 Using quad on integrals from Romberg assignment

### 3.1 Question 1, 2

#### Code

```
def f1(x):
    return ((sp.jv(3,2.7*x))**2)*x

def f2(x):
    return ((sp.kv(3,1.2*x))**2)*x

import scipy.integrate as si
ans1=si.quad(f1,0,1,full_output=0,epsabs=1e-12,epsrel=1e-12)
print(ans1) # Using quad function

>(0.009969186534269647, 1.106802042712923e-16)

ans2=si.quad(f2,1,np.inf,full_output=0,epsabs=1e-12,epsrel=1e-12)
print(ans2)

>(3.0924507786178372, 8.110039530734295e-13)
```

When we are breaking the functions and then taking the integral gives us a better answer compared to taking the whole integrand in one go. This behaviour is similar to the one seen in trapzd function for trapezoidal method.

### 3.2 Question 3

### Code: Using Gauss-Legendre in f1

```
\begin{array}{l} \text{import gauss\_quad as gq} \\ x, \text{w=gq.gauleg} \left(0\,, 1\,, 20\right) \\ \text{val=0} \\ \text{for i in range} \left(\text{len}\left(x\right)\right) : \\ \text{val+=} \text{f1} \left(x\left[\,i\,\right]\right) * w\left[\,i\,\right] \\ \text{print} \left(\text{np.abs} \left(\,\text{val-ans1}\left[\,0\,\right]\right)\right) \\ > & 1.682681771697503 \,\text{e}{-16} \end{array}
```

### Code: Using Gauss-Laguerre in f2

```
\begin{array}{l} \operatorname{def} \ \operatorname{func2}(z)\colon \\ \operatorname{return} \ f2(z+1)*\operatorname{m.exp}(z) \ \#\operatorname{shifting} \ \operatorname{it} \ \operatorname{by} \ 1 \ \operatorname{such} \ \operatorname{that} \ \operatorname{the} \ \operatorname{integral} \ \operatorname{is} \ \operatorname{from} \\ \operatorname{zero} \ \operatorname{to} \ \operatorname{infinity} \ \operatorname{and} \ \operatorname{not} \ \operatorname{from} \ 1 \ \operatorname{to} \ \operatorname{infinity} \\ \operatorname{x,w=gq.gaulag}(105,0) \ \#\operatorname{Quad} \ \operatorname{is} \ \operatorname{giving} \ 13\operatorname{th} \ \operatorname{order} \ \operatorname{accuracy} \ \operatorname{for} \ 105 \ \operatorname{eval} \, , \ \operatorname{but} \\ \operatorname{Gauss-Laguerre} \ \operatorname{is} \ \operatorname{giving} \ 12\operatorname{th} \ \operatorname{order} \, . \\ \operatorname{val=0} \\ \operatorname{for} \ \operatorname{i} \ \operatorname{in} \ \operatorname{range}(\operatorname{len}(x))\colon \\ \operatorname{val+=func2}(x[\operatorname{i}])*\operatorname{w[i]} \\ \operatorname{print}(\operatorname{val}) \\ \operatorname{print}(\operatorname{np.abs}(\operatorname{val-ans2}[0])) \ \#\operatorname{alpha} \ \operatorname{is} \ \operatorname{zero} \\ \\ 3.09245077861445 \end{array}
```

The alpha is zero here, however, according to wiki, this form of integration is analytically correct but numerically stable.

### 3.3 Question 4: Using Romberg to evaluate f1

f1 represents the function

 $3.3870684035264276e{-12}$ 

$$I_1 = \int_0^1 J_v^2(ku) \, u du \tag{11}$$

### Code:

```
import romberg as r integral=r.qromb(f1,0,1,1.e-12) print(integral)
```

> (0.009969186534269642, -1.0555978304531426e-16, 129)

We can see that the error is of order 16.

## 3.4 Question 5: Using Romberg to evaluate f2

```
 \begin{array}{l} \text{def modified\_f2}\,(x)\colon \\ A=\!20 \\ \text{return } (sp.kv(3,1.2*A*np.tan(x))**2)*(A**2)*np.tan(x)/(np.cos(x)**2) \\ \# \text{Visalizing the function after modification but converting Nan values to zero } x=\!np.array(range(1,20)) \\ x=\!modified\_f2\,(x) \\ \text{for i in range(len(x)):} \\ \text{if np.isnan}\,(x[i])\colon \\ x[i]=\!0 \\ \text{fig = plt.figure(figsize=(20,10))} \\ \text{fig.add\_subplot}\,(1,\ 2,\ 1) \\ \text{plt.semilogy}\,(range(1,20),x,"c") \\ \text{plt.semilogy}\,(range(1,20),x,"mo") \\ \text{plt.grid}\,() \end{array}
```

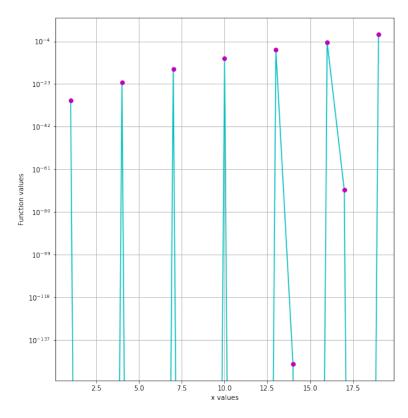

Figure 3

### Code:

```
import romberg as r integral=r.qromb(modified_f2 ,m.pi/4,m.pi/2,1.e-12) #Closed Romberg print(integral)  > (1.1029478499177205e-21, -7.071826959966638e-36, 2049)  integral2=rom.qromo(modified_f2 ,m.pi/4,m.pi/2,1.e-12) #Open Rpmberg print(integral2)  > (1.1029478499176691e-21, 4.799818695639193e-34, 2187)
```

It can be observed that changing the values of A changes the order of accuracy.
